Workshop Outline

Day 1:

An Introduction to Missing Data and Bayesian Statistics with Blimp

Day 2:

- Finish remaining material from Day 1.
- Latent Variable Models with Blimp

Day 1's Overview

- Missing Data Processes
- Introduction to Bayesian Statistics
- Fitting Regression Models in Blimp
- Understanding Blimp Output
- Incomplete Categorical Variables
- Interaction Effects in Blimp

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

-

Why Bayesian statistics?

Things Bayesian approaches are good at...

- Direct estimation for complex models with missing data
- Introduction of mixed response metrics (normal, binary, ordinal, etc.)
- Nonlinear effects (interactions, curvilinear, etc.)
- Multilevel data (random effects, interactions, heterogenous variance)
- Complex latent variable modeling (interactions, multilevel)

Brian T. Keller (University of Missouri)

7

Missing Data Processes

Introduction to Missing Data

Generally, statistical methods are developed to make population inferences from *rectangular data sets*, where the rows are observations and the columns represent random variables.

Data				
Υ	X

Data

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

- Missing or incomplete data is concerned with instances where some entries in our data set are
- Missing data can occur on different types of variables in the design: covariates, mediators, moderators, final outcome variables of interest.

Data

Y	X
4	2

@ Yonsei University (June 25, 2024)

- 4

Two Distinct Concepts

- The missingness pattern describes the configuration of the observed and missing values in a data set.
- The missingness mechanism describes the relationship between the missingness and the values of variables in the data.

Missing Data Mechanisms

- Conceptually, we are treating the missing data indicator as a binary variable representing if an observation for a variable is missing (M = 1) or observed (M = 0).
- The missing data mechanism is a classification of the relationship between the missing data indicator to the variables in the data set.
- Missingness may be independent of the data, or it could relate to the observed or missing parts (or both).

Brian T. Keller (University of Missouri)

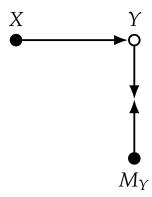

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

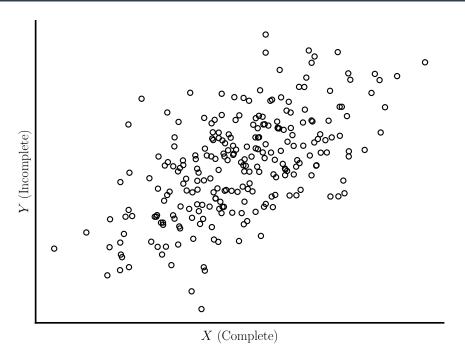

1.

Missing Completely at Random (MCAR)

Missing completely at random stipulates that the probability of observations being missing is *unrelated* — be it directly or via spurious relationships — to the data.

Scatterplot of X and Y

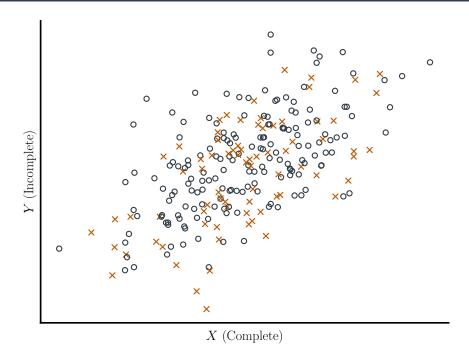

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

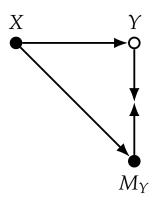

11

MCAR – Scatterplot of Missing and Observed Values

Missing at Random (MAR)

Missing at random stipulates that the probability of observations being missing is related — be it directly or via spurious relationships — to the *observed data but not the missing data*.

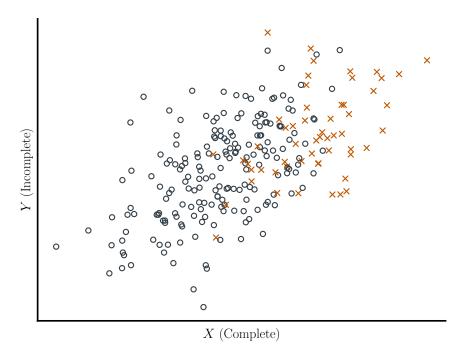

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

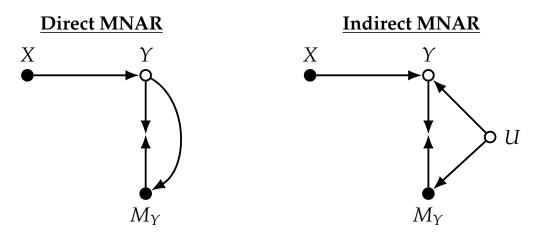

11

MAR – Scatterplot of Missing and Observed Values

Missing Not at Random (MNAR)

Missing not at random stipulates that the probability of observations being missing is related — be it directly or via spurious relationships — to the *missing data*.

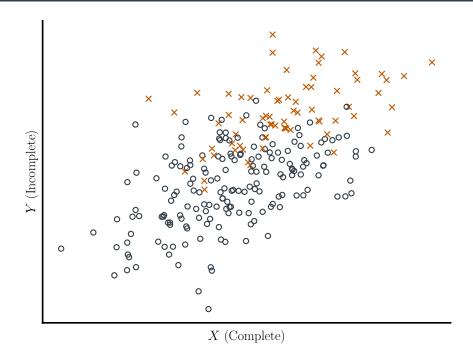

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

- - -

MNAR – Scatterplot of Missing and Observed Values

Mechanisms Summary...

- Missing completely at random ⇒ haphazard missingness
- Missing at random ⇒ systematic missingness solely related to observed values
- Missing not at random ⇒ systematic missingness related to the value of the missing observation

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

21

Working Assumptions

- Bayesian methods and modeling approach we discuss assume that the missing process is MAR.
- Missing at random is untestable because it involves knowing the "Truth" about the unobserved scores.
- These methods can extended to MNAR with additional modeling (but not discussed in this workshop).

Introduction to Bayesian Statistics

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

23

Why Bayesian statistics?

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

21

Frequentist

- Probability is defined by an event's hypothetical relative long run frequency.
- Probability is applied to hypothetical future sampled data (e.g., sampling distributions for estimates).
- Parameters are 'fixed' at some unknown value in the population.

Bayesian

- Probability is defined by one's degree of belief
- Probability can be applied to anything really.
- Parameters are 'random' and represented by a probability distribution of plausible values.

 We try to estimate the distribution based on one's belief.

² If you don't know, probably what you are.

Frequentist Approach

- A Frequentist point of view finds the single fixed value that is most likely given the sample we observed (via maximum likelihood, FIML).
- FIML uses the probability of the data given the parameter values—the likelihood of the data given a fixed parameter in the population;

 P (data | parameters).

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

2.

Bayesian Approach

- Bayesian takes this one step further and estimates the probability of the parameters given the data—P (parameters | data).
- Because most parameters are continuous, this means we characterize all values that the parameter potentially could take via a probability distribution.

How do we obtain the probability of the parameters given the observed data when what we have is the reverse?

$$P ext{ (parameters } | ext{ data}) \neq f ext{ (data } | ext{ parameters })$$
What we want to know What we have

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

.

Bayes' Theorem

$$P\left(\text{parameters} \mid \text{data}\right) = \frac{P\left(\text{data} \mid \text{parameters}\right) P\left(\text{parameters}\right)}{P\left(\text{data}\right)}$$

P (parameters | data): The posterior distribution. The probability of the parameters given the data (what we want).

Bayes' Theorem

$$P\left(\text{parameters} \mid \text{data}\right) = \frac{P\left(\text{data} \mid \text{parameters}\right) P\left(\text{parameters}\right)}{P\left(\text{data}\right)}$$

- *P* (data | parameters): The likelihood. The probability of the data given the parameters (what we observe).
- *P* (parameters): The prior distribution. The probability of the parameters overall. This represents the a priori knowledge we have about the parameters.

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

.

Bayes' Theorem

$$P\left(\text{parameters} \mid \text{data}\right) = \frac{P\left(\text{data} \mid \text{parameters}\right) P\left(\text{parameters}\right)}{P\left(\text{data}\right)}$$

P (data): A scaling term that makes the sum of P (parameters | data) equal one. We are not interested in this.

Prior Distribution

- Bayesian analyses require prior distributions that encode our beliefs about the parameter values prior to analyzing the data.
- Blimp adopts non-informative (diffuse) priors by default that impart as little information as possible (i.e., let the data do the talking).
- A diffuse prior for means and coefficients conveys that all possible parameter values are equally likely (a flat distribution).

Brian T. Keller (University of Missouri)

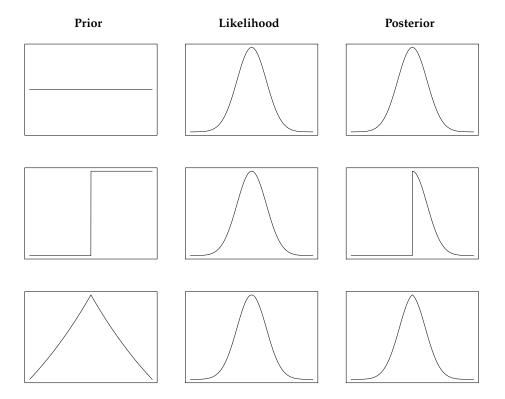

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

2

Posterior Distributions

- The prior and likelihood function as two data sources that merge to define the posterior distribution of the parameters.
- The posterior describes the distribution of plausible values that could have produced the particular data given our model.
- Instead of estimates varying around a fixed parameter (Frequentist), the parameters vary around a fixed data set (Bayesian).

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

0.5

Bayesian Statistics and this Workshop

- We will largely ignore the philosophical debate regarding what probability ought to represent.
- Instead, we will focus on using it practically and in a framework that does not require you to be a Bayesian.
- The priors we will use are generally diffuse and provide little information. These will generally fall under what is called an 'uninformative' or a 'weakly informative' prior.

Workshop Data

Chronic Pain Data – Variable Definitions

Name	Definition	Missing %	Range
disab	Psychosocial disability composite	9.1	10 to 34
depress	Depression composite score	13.5	7 to 28
severity	Severe pain dummy code	7.3	0 or 1
male	Biological sex dummy Code	0.0	0 or 1

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

25

One Predictor Regression Illustration

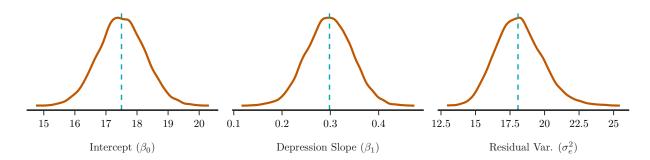

A study that is investigating the relationship of psychological disability predicted by depression scores.

$$disab_i = \beta_0 + \beta_1 (depress_i) + e_i$$

Both measures have missing values that must be handled.

Posterior Distributions

	Median	SD	CI 2.5%	CI 97.5%
Intercept (β_0)	17.50	0.74	16.05	18.97
Depression Slope (β_1)	0.30	0.05	0.21	0.39
Residual Var. (σ_e^2)	18.08	1.69	15.17	21.79

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

2

Estimator Comparison

Two approaches provide numerically equivalent results and inferences.

	Bayesian				Frequentist (FIML)			
	Median	SD	CI 2.5%	CI 97.5%	Estimate	SE	CI 2.5%	CI 97.5%
Intercept (β_0)	17.50	0.74	16.05	18.97	17.55	0.74	16.10	19.00
Depression Slope (β_1)	0.30	0.05	0.21	0.39	0.30	0.05	0.21	0.39
Residual Var. (σ_e^2)	18.08	1.69	15.17	21.79	17.49	1.68	14.19	20.79

Markov Chain Monte Carlo (MCMC)

- A Bayesian analysis involves estimating the distribution of model parameters and the missing values by sampling methods.
- Typically, MCMC breaks the complex problem involving multiple unknown quantities (parameters and missing values) into separate steps.
- Each step estimates one unknown at a time, treating the current values of all other quantities as known constants.

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

1.

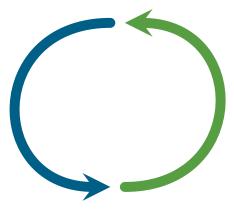

MCMC Estimation

Do for t = 1 to T iterations:

- Estimate focal model parameters given filled-in data
- Estimate predictor model parameters given filled-in data
- Fill-in missing outcome scores given focal model parameters
- Fill-in missing predictor scores given focal and predictor model parameters

Repeat

Estimate Regression Models

Fill-in Missing Values

What do I mean by "Estimation"?

- A posterior distribution characterizes the probability of a parameter's "true" value given the data we observed and the model.
- MCMC uses computer simulation (random number generation) to sample from this distribution. We can then use descriptive statistics to summarize the posterior distribution.
- Parameters and missing data scores are unknown, so their values constantly change with new samples during the MCMC sequence.

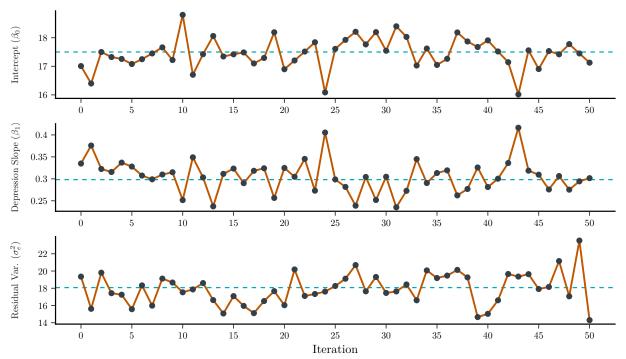

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

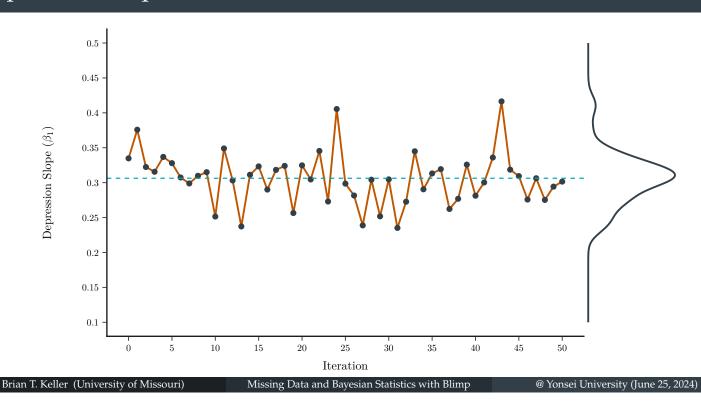

@ Yonsei University (June 25, 2024)

4

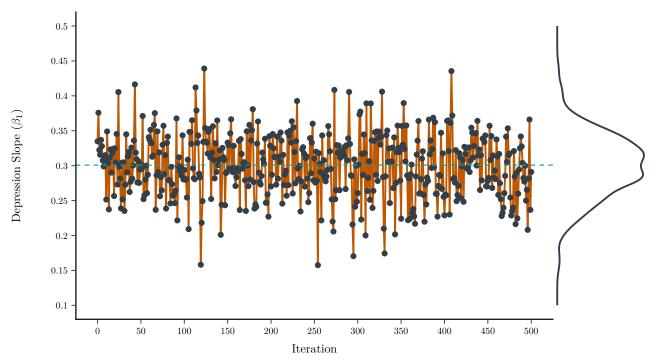

Parameters from 50 MCMC Iterations

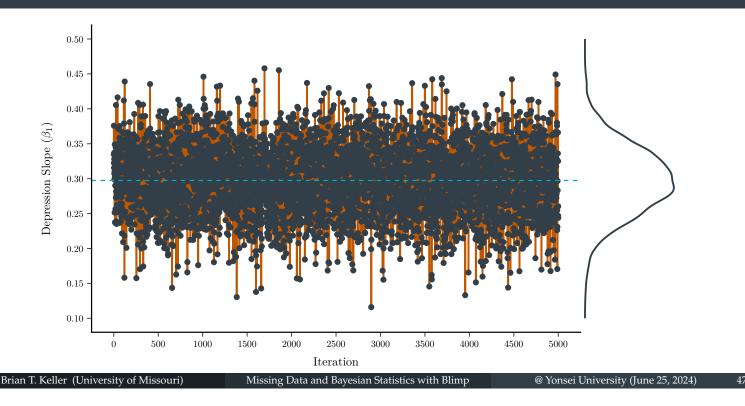

Depression Slope from 50 MCMC Iterations

Depression Slope from 500 MCMC Iterations

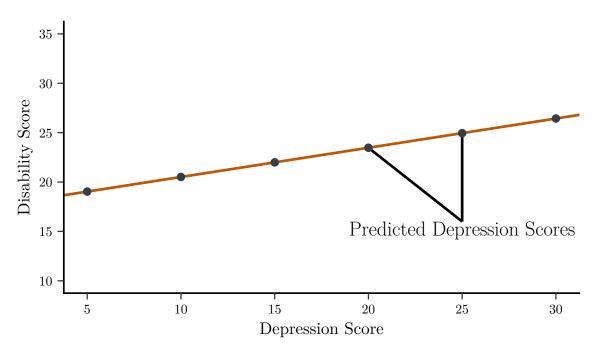

Depression Slope from 5000 MCMC Iterations

Filling-in Missing Data (Imputation)

- Missing scores are filled-in or "imputed" by randomly drawing replacement scores from a distribution of plausible values.
- Like parameters, we draw a new set of imputed scores for each missing variable in each iteration.
- Imputing predictors is more complex than imputing outcomes.

Predicted Scores on Outcome

51

Incomplete Predictors

- Incomplete predictor variables require a model and distribution.
- We must model the multivariate distribution of our outcome and predictors.
- Using a pure multivariate distribution can *misspecify* the data distribution and cause biased estimates.

Factored Regression Modeling

Blimp's Modeling Framework

Factored Regression modeling invokes separate regression models (and distributions) for incomplete predictors and outcomes.

$$f(\text{outcomes}, \text{predictors}) = f(\text{outcomes} \mid \text{predictors}) \times f(\text{predictors})$$

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

57

 $f(\text{outcomes}, \text{predictors}) = f(\text{outcomes} \mid \text{predictors}) \times f(\text{predictors})$

$\frac{\text{Predictor Model(s)}}{X_1}$ X_2 X_3 Outcome Model(s)

Returning to Simple Regression Example...

Factorization:

$$f(\texttt{disab}, \texttt{depress}) = f(\texttt{disab} \mid \texttt{depress}) \times f(\texttt{depress})$$

Fitted Models:

$$f(exttt{disab} \mid exttt{depress})
ightarrow \qquad exttt{disab}_i = eta_0 + eta_1 \left(exttt{depress}_i
ight) + e_i$$
 $f(exttt{depress})
ightarrow \qquad exttt{depress}_i = \gamma_0 + r_i$

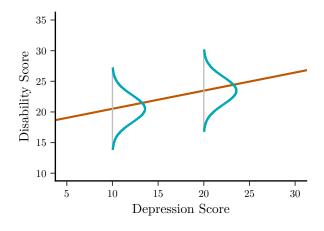

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

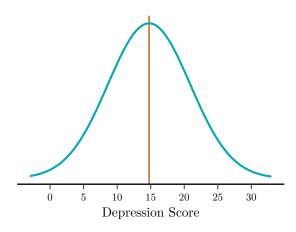

@ Yonsei University (June 25, 2024)

Distributions...

$$f(exttt{disab} \mid exttt{depress})
ightarrow ext{disab}_i = eta_0 + eta_1 \left(exttt{depress}_i
ight) + e_i$$

Imputing Incomplete Predictors

- The missing predictor appears in two models (at least):
 - ➤ A predictor in the focal model
 - ➤ As an outcome in it's own model
- The distribution for the missing predictor is a composite of the two distributions:

$$f(\text{depress} \mid \text{disab}) \propto f(\text{disab} \mid \text{depress}) \times f(\text{depress})$$

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

The distributions must be analytically solved based on the factorization.

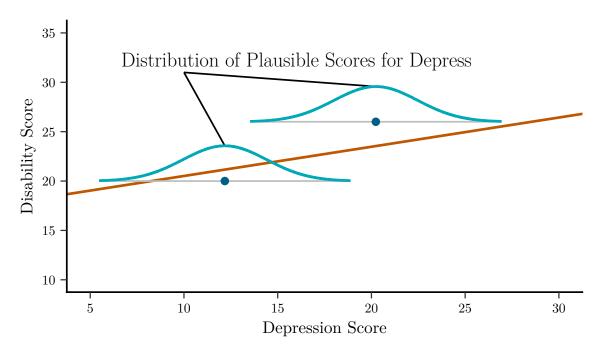

$$f(\text{depress} \mid \text{disab}) \propto f(\text{disab} \mid \text{depress}) \times f(\text{depress})$$

The software will do this for you, but as an example:

$$ext{depress}_i = rac{\sigma_r^2 eta_1 \left(ext{disab}_i - eta_0
ight) + \sigma_e^2 \gamma_0}{\sigma_r^2 eta_1^2 + \sigma_e^2}$$

$$\sigma_{\text{depress}|\text{disab}}^2 = \frac{\sigma_e^2 \sigma_r^2}{\sigma_r^2 \beta_1^2 + \sigma_e^2}$$

Understanding Blimp Output

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

MCMC Convergence

- MCMC "converges" when the posterior distributions are stationary.
- This means that parameter estimates oscillate around a stable mean, and the variation does not change with additional iterations.
- We should always set burn-in iterations greater than number of iterations needed for "convergence."

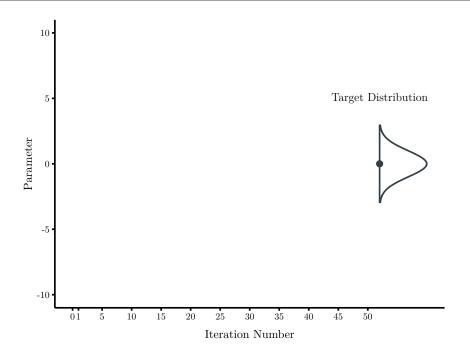

- The simulative algorithm MCMC uses requires monitoring of convergence.
- Convergence can loosely be thought of as determining if our algorithm has correctly drawn from the distribution it is trying to simulate from.
- We need to monitor convergence on every parameter in our model.

Bayesian Diagnostics

Diagnostics are used for two main purposes:

- To determine if we have issues estimating the model.
- To determine the appropriate burn-in iterations (i.e., how many iterations we will "throw away" before starting to sample from the distributions).

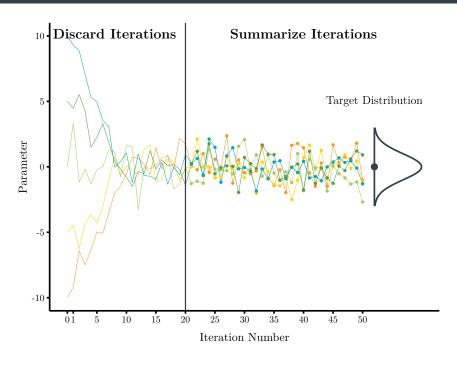

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

0

50 Iterations for 5 Chains

Potential Scale Reduction Factor

- The potential scale reduction factor (PSR, PSRF, Rhat, \hat{R}) compares parameter distributions generated from multiple unique MCMC processes.
- MCMC converges when the two chains give estimates with same mean and spread.
- A rule of thumb for PSRF is that convergence has been reached if the PSRF is constantly below 1.05.

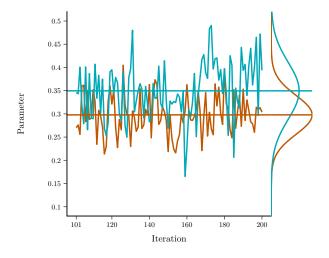

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

gi

General Recommendations

- Look at the *PSRF* statistics. If the highest PSR falls below 1.05 or so and consistently stays below that then run a few extra iterations and use that as burn-in value.
- Most likely your model is not supported by your data (i.e., you do not have enough information to estimate the model). So simplify the model.

You can never run too many iterations!

Error on the side of caution always.

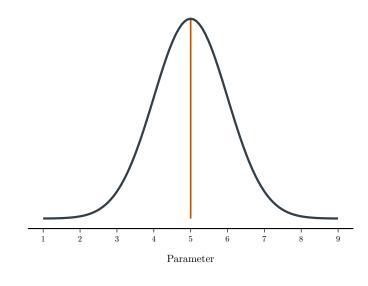

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

Posterior Mean and Median

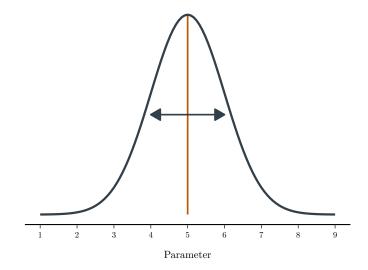

- The posterior *mean* and *median* quantifies the parameter value most likely to be on average.
- They can be considered analog to point estimates in a standard Frequentist analysis.

Posterior Standard Deviation

- The posterior *standard deviation* quantifies the

 uncertainty we have in knowing
 the parameter value.
- This is similar to a Frequentist standard error but without reference to repeated sampling.

Brian T. Keller (University of Missouri)

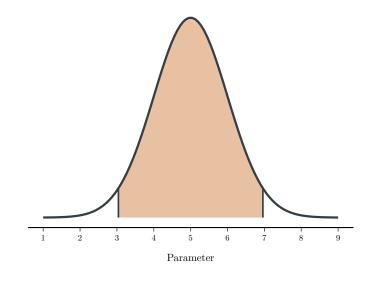

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

ga

95% Credible Intervals

- The posterior 95% credible interval quantifies the limits that span 95% of the parameter's range.
- This is similar to a Frequentist confidence interval but references a range of highly plausible values.

Analysis Model

A study that is investigating the relationship of psychological disability predicted by depression scores, perceived control over pain, and biological sex.

$$\mathtt{disab}_i = \beta_0 + \beta_1 \left(\mathtt{depress}_i\right) + \beta_2 \left(\mathtt{control}_i\right) + \beta_3 \left(\mathtt{male}_i\right) + e_i$$

Reminder! These are partial regression coefficients.

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

11

Example Interpretation

- For two participants who share the same biological sex and perceived control of pain, scoring one point higher on the depression scale is associated with a 0.257 increase on the psychological disability construct.
- The slope is "significantly different" from zero because zero is not within the 95% credible intervals (0.163, 0.351).

Do I have enough iterations?

- MCMC estimates are not independent across iterations.
- The effective sample size (N_EFF) estimates the number of independent samples that are used in the posterior summaries.
- The literature recommends at least 100 independent MCMC samples per parameter (Gelman et al., 2014; p. 267).

What about the predictor model?

- Blimp also supplies output for the specified predictor model.
- These parameter estimates can be considered nuisance parameters—that is, parameters we don't generally care about.
- We still need to monitor their convergence, including looking at PSRF and effective sample sizes.

Bayesian Wald Test

Asparouhov and Muthén (2021) proposed a Bayesian Wald test that mimics familiar likelihood-based Wald tests.

$$T = (\boldsymbol{\theta} - \boldsymbol{\theta}_0) \, \boldsymbol{\Sigma}_{\boldsymbol{\theta}}^{-1} \, (\boldsymbol{\theta} - \boldsymbol{\theta}_0)$$

T is the sum of squared standardized differences (chi-square metric) between the posterior means and null hypothesis.

Reporting Template – Diagnostics

We used Bayesian methods in Blimp 3.2 (Keller & Enders, 2021) to treat missing values under the assumption that missingness is random after conditioning on the observed data. Potential scale reduction factor convergence diagnostics (Gelman & Rubin, 1992) from a preliminary run indicated that a burn-in period of 2,500 iterations was sufficiently conservative. Based on this information, we used four MCMC chains with random starting values to generate posterior summaries consisting of 10,000 estimates following the initial burn-in period. We verified this setting was sufficient by examining the effective number of independent MCMC samples for each parameter, all of which were greater than the recommended value of 100 (Gelman et al., 2014, p. 287).

Reporting Template – Results

Table 1 displays the posterior summaries from the analysis using uninformative priors. The posterior medians and standard deviations are analogous to frequentist point estimates and standard errors, and the 95% credible interval limits are akin to confidence intervals. These quantities make no reference to repeated samples but instead convey parameter values that are consistent with the observed data. Given the same assumptions and data, Bayesian and likelihood-based missing data handling procedures are numerically equivalent (Enders, 2022).

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

Reporting Template – APA Table

Table 1

Parameter Summary from Bayesian Regression Analysis

	Median	SD	CI 2.5%	CI 97.5%
Intercept (β_0)	21.98	1.55	18.97	25.00

R^2	0.21	0.05	0.12	0.30

Reporting Template – Results Continued

Collectively, the predictors explained approximately 21% of the variation in psychological disability scores. The Bayesian Wald test (Asparouhov & Muthén, 2021) of the full model was statistically significant, $\chi^2(3) = 55.80$, p < 0.001. While controlling for biological sex, depression scores exhibited a significant positive association with psychological disability scores ($\beta = 0.26$, 95% CI = (0.16, 0.35)), and the measure of perceived control of pain was inversely related to psychological disability ($\beta = -.18$, 95% CI = -.28, -.07)).

400

Incomplete Categorical Predictors in Blimp

Factored Regression

- One advantage of Factored Regression is its ability to easily incorporate variables of different response metrics.
- By breaking up the complex multivariate distribution into easier chunks, it is easier to appropriately model the response metric.
- ▶ Blimp can incorporate binary, ordinal, and nominal predictor variables with minor changes to the Blimp syntax.

Brian T. Keller (University of Missouri)

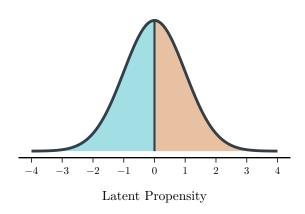

Missing Data and Bayesian Statistics with Blimp

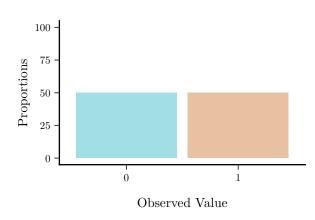

@ Yonsei University (June 25, 2024)

120

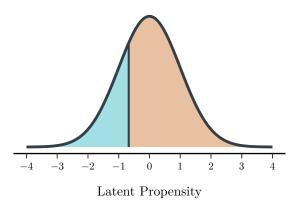

Latent Propensity Distribution

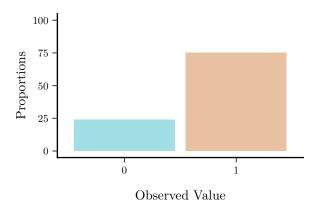

A threshold parameter divides the latent distribution into segments, with areas under the curve matching the observed proportions.

When the threshold changes (or intercept) changes, then the proportion changes as well.

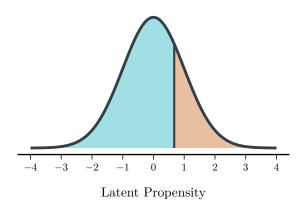

Brian T. Keller (University of Missouri)

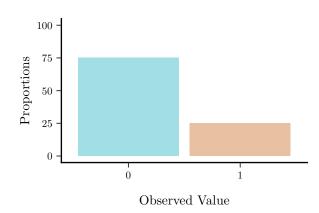

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

13

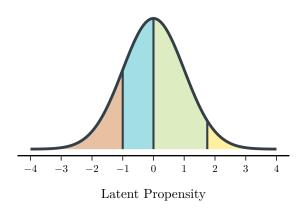

When the threshold changes (or intercept) changes, then the proportion changes as well.

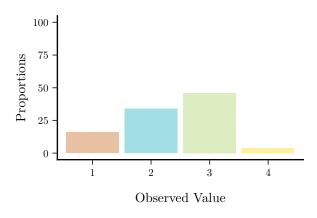

Latent Propensity Distribution

Ordinal variables are defined by multiple thresholds to divide the propensity into multiple ordered categories.

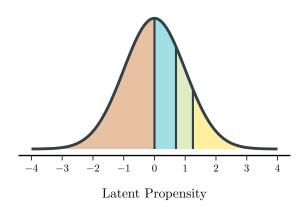

Brian T. Keller (University of Missouri)

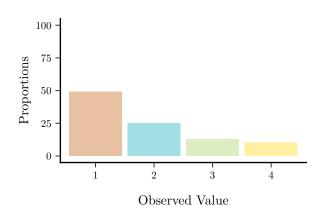

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

. .

Changing the thresholds produce different distributions of the ordinal responses.

Treating the Latent Responses as Missing

- The latent response scores can be considered missing data that must be imputed.
- MCMC treats the latent responses like any other incomplete variable with the caveat that we know the observed metric when the observed response is complete.

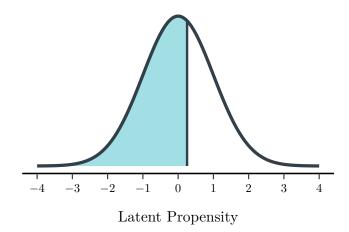

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

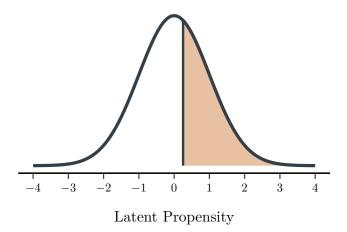

@ Yonsei University (June 25, 2024)

. . .

For a binary variable, when the observed value is 0, we impute based on values <u>below</u> the threshold:

When the observed value is 1, we impute based on values <u>above</u> the threshold:

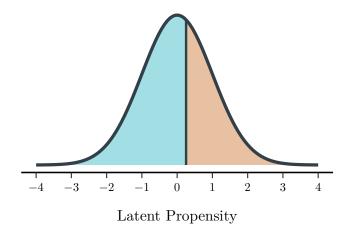

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

When the observed value is *missing*, we impute based on values across the <u>entire</u> distribution:

Workshop Data

Chronic Pain Data – Variable Definitions

Name	Definition	Missing %	Range
disab	Psychosocial disability composite	9.1	10 to 34
depress	Depression composite score	13.5	7 to 28
control	Perceived pain control composite	0.0	6 to 30
severity	Severe pain dummy code	7.3	0 or 1
male	Biological sex dummy Code	0.0	0 or 1

120

Analysis Model

A study that is investigating the relationship of psychological disability predicted by depression scores, coded severe pain (0 or 1), perceived control over pain, and biological sex.

$$\mathtt{disab}_i = \beta_0 + \beta_1 \left(\mathtt{depress}_i\right) + \beta_2 \left(\mathtt{severity}_i\right) + \beta_3 \left(\mathtt{control}_i\right) + \beta_4 \left(\mathtt{male}_i\right) + e_i$$

Factored Regression Model

With the additional incomplete variable (severity) our factorization of outcome and incomplete predictors is as follows:

```
f(\text{disab} \mid \text{depress}, \text{severity}, \text{control}, \text{male}) \times \\ f(\text{depress}, \text{severity} \mid \text{control}, \text{male})
```

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

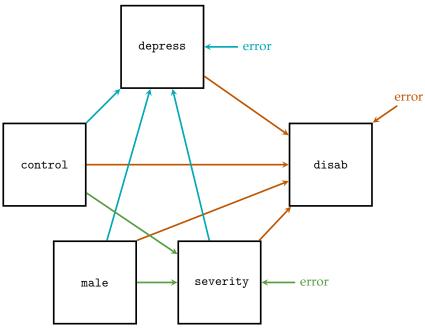

. . .

We can further split the predictor model into two univariate models, giving us three full models we must specify:

```
f(	ext{disab} \mid 	ext{depress, severity, control, male}) \times \\ f(	ext{depress} \mid 	ext{severity, control, male}) \times \\ f(	ext{severity} \mid 	ext{control, male})
```

$f(disab \mid depress, control, male) \times$

 $f(\text{depress} \mid \text{severity}, \text{control}, \text{male}) \times f(\text{severity} \mid \text{control}, \text{male})$

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

14

Example Interpretation

- Comparing two participants who share the same on all other predictors (biological sex, perceived control of pain, and depression score), endorsing severe pain or not is associated with a 1.57 increase on the psychological disability construct.
- The slope is "significantly different" from zero because zero is not within the 95% credible intervals (0.368, 2.764).

Interaction Effects in Blimp

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

140

Moderated Regression (Interaction Effects)

- ► Moderation occurs when the magnitude of an association of a focal predictor (*X*) depends on a third variable (moderator; *M*).
- Moderated regressions answer the question, for whom does an effect apply?

Moderated Regression Model

A moderated regression adds the product of *X* and *M* as a predictor:

$$y_i = \beta_0 + \beta_1(x_i) + \beta_2(m_i) + \beta_3(x_i \times m_i) + e_i$$

 β_3 : Captures the change in the β_1 slope for every one-unit increase of M.

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

- -

Incomplete Variables in Product Terms

- Factored regression readily handles interactive and other nonlinear effects
- Product terms appear as a deterministic function in the focal regression model.
- The models for the predictor variables remain unchanged.

Conditional Effects Analysis (Simple Effects)

We can rearrange terms to give the conditional effect of a focal predictor (X) on a function of the moderator (M).

$$y_i = \beta_0 + \beta_1 x_i + \beta_2 m_i + \beta_3 x_i m_i + e_i$$

$$= (\beta_0 + \beta_2 m_i) + (\beta_1 x_i + \beta_3 x_i m_i) + e_i$$

$$= (\beta_0 + \beta_2 m_i) + (\beta_1 + \beta_3 m_i) x_i + e_i$$

$$y_i = (\text{simple intercept}) + (\text{simple slope}) x_i + e_i$$

Conditional Effects Analysis in Blimp

ightharpoonup Compute for when male = 0:

$$\begin{aligned} \mathtt{disab}_i &= (\beta_0 + \beta_2 \times 0) + (\beta_1 + \beta_3 \times 0) \left(\mathtt{depress}_i - \mu_{\mathtt{dep}} \right) + e_i \\ &= (\beta_0) + (\beta_1) \left(\mathtt{depress} - \mu_{\mathtt{dep}} \right) + e_i \end{aligned}$$

Compute for when male = 1:

$$\begin{split} \mathtt{disab}_i &= (\beta_0 + \beta_2 \times 1) + (\beta_1 + \beta_3 \times 1) \left(\mathtt{depress}_i - \mu_{\mathtt{dep}} \right) + e_i \\ &= (\beta_0 + \beta_2) + (\beta_1 + \beta_3) \left(\mathtt{depress}_i - \mu_{\mathtt{dep}} \right) + e_i \end{split}$$

Reporting Template – Diagnostics

We used Bayesian methods in Blimp 3.2 (Keller & Enders, 2021) to treat missing values under the assumption that missingness is random after conditioning on the observed data. Potential scale reduction factor convergence diagnostics (Gelman & Rubin, 1992) from a preliminary run indicated that a burn-in period of 5,000 iterations was sufficiently conservative. Based on this information, we used four MCMC chains with random starting values to generate posterior summaries consisting of 10,000 estimates following the initial burn-in period. We verified this setting was sufficient by examining the effective number of independent MCMC samples for each parameter, all of which were greater than the recommended value of 100 (Gelman et al., 2014, p. 287).

Reporting Template – Results

Table 1 displays the posterior summaries from the analysis using uninformative priors. The posterior medians and standard deviations are analogous to frequentist point estimates and standard errors, and the 95% credible interval limits are akin to confidence intervals. These quantities make no reference to repeated samples but instead convey parameter values that are consistent with the observed data. Given the same assumptions and data, Bayesian and likelihood-based missing data handling procedures are numerically equivalent (Enders, 2022).

Brian T. Keller (University of Missouri)

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

Reporting Template – APA Table

Table 1

Parameter Summary from Bayesian Regression Analysis

	Median	SD	CI 2.5%	CI 97.5%
Intercept (β_0)	22.08	0.39	21.31	22.84
Depression Slope (β_1)	0.41	0.06	0.28	0.53
Male Slope (β_2)	-0.35	0.56	-1.434	0.731
Depression \times Male (β_3)	-0.22	0.09	-0.41	0.04
R^2	0.19	0.05	0.11	0.28

Reporting Template – Results Continued

Collectively, the predictors explained approximately 19% of the variation in psychological disability scores. The 95% credible intervals for the interaction effect did not contain zero within the interval (-0.41, -0.04), suggesting that biological sex moderates the association between psychological disability and depression composite scores. The negative interaction coefficient indicates that the strength of the positive association between psychological disability and depression decreases for males compared to females. Conducting a conditional effects analysis reveals that the strength of association is about half for men compared to women. Figure 1 displays the simple slopes for men and women.

Missing Data and Bayesian Statistics with Blimp

@ Yonsei University (June 25, 2024)

17

Composite Scores with Item Level Missingness

- Often, psychological constructs are composites of multiple items summed or averaged together.
- When one item is missing, the entire composite score is considered missing. This can lead to a loss of information and reduced statistical power.

Workshop Data

Chronic Pain Data – Variable Definitions

Name	Definition	Missing %	Range
disab	Psychosocial disability composite	9.1	10 to 34
depress	Depression composite score	13.5	7 to 28
male	Biological sex dummy Code	0.0	0 or 1
